ABSTRACT:

A method for estimating a value of a diffusion tensor includes obtaining, from a plurality of test subjects, DT-MRI data from which an initial estimate of the tensor can be derived. Values indicative of int-subject variation and inter-subject variation in the data are then determined. These values are used to determine a subject-specific additive offset for adjusting the DT-MRI data.

ABSTRACT:

The invention provides a reproducible, objective quantification technique that
reliably segments white matter structures. The technique receives a seed voxel
within the white matter structure from an individual, determines thresholds and
selection criteria, creates a binary mask based on the at least one threshold and
the at least one selection criteria and calculates the boundary of the white matter
structure based on the binary mask. A magnification factor is applied to each
component of the eigenvectors of voxels. Boundary voxels are determined wherein
each of the boundary voxels has a magnitude above a predetermined value and is
located next to a voxel having a magnitude below the predetermined value. A vector
is drawn from the seed voxel to a boundary voxel and the boundary voxels are
connected together, thereby forming the region of interest within the connected
boundary voxels.

ABSTRACT:

The present invention relates to methods, software and systems for monitoring
fluctuations in magnetic resonance signals. These methods may be used for
measurements of the human brain and nervous system, and may be used for measuring
electric currents and electromagnetic fields internal to an object. This method may
include the use of a reference signal to accomplish differential recording of
electromagnetic fields from two or more spatial locations.

ABSTRACT:

Quantified differences, such as chi.sup.2 error parameters, between a mono-
exponential, logarithmic best fit of a series of line scan diffusion-weighted
magnetic resonance signals taken over a range of b-factors between about 100 and
about 5000 sec/mm.sup.2 are obtained. The quantified differences so generated are
displayed as an image wherein the brightness of each pixel depends upon the size of
its associated quantified difference. The resulting image is characterized by high
signal to noise ratio and distinctness between varying tissue types.

ABSTRACT:

Methods for evaluating information about the structure and function of neural
circuits in the brain can be used for diagnosis and gene identification. Exemplary
methods and data management features consolidate relationships within multi-
dimensional complex data sets, erg., data sets that include systems biology
measures, such as those obtained from neuroimaging, and, optionally also genetic
measures, e.g., from the same individuals.
